ABSTRACT—Many ethnographic reports refer to a large, “pineapple-like” fern rootstock which was an important native root vegetable in northwestern North America. It is suggested here that the primary, most commonly used edible type is Dryopteris expansa, with other, related species having been used in some localities and under some circumstances. The rootstocks were cooked in pits, often in winter when food was scarce. They are seldom eaten today and are known primarily by native elders. Several botanical identifications for this food have been suggested in Dryopteris, Athyrium, and other fern genera. Species verification has been complicated by lack of botanical expertise among early reporters, difficulty in recalling the fern characters by elders, and taxonomic complexities of the ferns. Rootstocks of D. expansa were harvested by the Nuu-chah-nulth at Bella Coola, cooked, and prepared for nutrient analyses. Proximate composition and energy are similar to that of the common potato, but Ca, Mg, Zn, Cu, and Mn were present in levels several-fold higher than that of potato.

RESUMEN.—Varios informes etnográficos se refieren a un raíz grande, “análogo a una piña,” de un helecho, que era una importante raíz alimenticia existía en el noroeste de Norteamérica. Se sugiere aquí que el tipo comestible primario, más comúnmente usado, es Dryopteris expansa, habiéndose empleado otras especies emparentadas en algunas localidades y en ciertas circunstancias. Las raíces se cocían en cavidades en el suelo, con frecuencia en el invierno cuando escaseaba la comida. En la actualidad, se comen muy poco, y son principalmente los ancianos indígenas quienes las conocen. Para este informe se han sugerido varias identificaciones botánicas en Dryopteris, Athyrium y otros géneros de helechos. La verificación de la especie se ha complicado por la falta de perfiles botánicos entre los primeros observadores, la dificultad en recordar las características de los
INTRODUCTION

Ferns are an important component of northwestern North American flora. The moist, mild coastal climate is ideal for the growth of many Pteridophyte species, and the diversity of habitats and microclimates is reflected in the diversity of species of ferns. Many reports have been published concerning the edibility of certain ferns by native peoples of the region (cf. Guenthner 1973; Turner 1975). The use of the rhizomes of western bracken fern (Pteridium aquilinum (L.) Kuhn) as food by Northwest Coast peoples has been well documented (cf. Norton 1979). The rhizomes of licorice fern (Polystichum glycyrrhiza D.C. Eaton) are also well known, even today, as a mouth sweetener and appetizer, although they were seldom eaten in any quantity (cf. Turner and Bell 1973; Turner 1973, 1975).

Perhaps the most intriguing and puzzling "fern food" is the rootstock recalled by many contemporary native elders and widely cited in the literature as a large, "pineapple-like," or "banana-like" clump of "flingers" which was cooked and eaten traditionally, both as a regular part of the diet and as emergency rations, along the coast from Oregon to Alaska and inland in British Columbia. There is probably more confusion about the identity of this edible fern rootstock, hereinafter called "wood fern" in a general context, than about any other traditional food plant in northwestern North America.

One of the earliest literature references to edible wood fern is by Gorman (1896), who identified it as Dryopteris spinaeosa f. 'Aquilinum aquilinum var. dilatatum (Wood-fern)" and provided the following account of its use by the Coast Tsimshian of southeastern Alaska (Gorman 1896:78-79):
[Wood-fern] ... is abundant in rich open woods near sea level, and the rootstock or caudex is highly relished by the natives, who cook and eat it in large quantities, it being the first vegetable food which they obtain in early spring. [It] ... is called “Ahh,” by the Tsimshians, who inform me that it is larger, sweeter, and of better flavor when grown under or in the vicinity of salmon berry bushes ... 

Ethnographers without botanical knowledge described the fern in the most general of terms. For example, J.F. Harrington, in his unpublished ethnographic notes, referred to it under a Squamish place name for a creek at Miller Bay (“Miller’s inlet”) on the Port Madison Indian Reservation in Washington:

Barbara Lane (personal communication to NJT, 1984) described the same Squamish fern in more detail, based on descriptions by Native people she consulted:

It[ts'akwe] is styled variously the “foossil fern,” “evergreen fern,” and “Indian banana.” It is a tall plant, and grows on logs in damp places. A cluster of edible pods is found at the bottom of the stalk, looking like one’s hands placed palm to palm. The Indians gathered these pods and baked them as they did chents, burying them in a pit with hot stones. The existence of these plants on the west side of the bay gave the place its name ... Miller Bay used to be called Squaub Bay, clearly a rendering of the native term for the fern.

Edible wood fern rootstocks, all having more-or-less similar descriptions and methods of gathering and preparation, have been described and identified as Dryopteris austriaca (Turner 1975; Heller 1976; Oswalt 1957), D. filicites (Turner 1973, 1975), D. dilatata (Kari 1987—"D. dilata," etc.), D. expansa (cf. Lepofsky et al. 1960), D. spinulosa (Gorman 1896—"Asplenium spinulosum var. dilatatum.", Harlan Smith, unpublished notes, 1920–1922—"Asplenium spinulosum"). Thelypteris limbo- sperma (Norton 1981), Cystopteris bulbifera ("Ksan, People of 1900), Athyrium filix-femina (Kari 1987; Harlan Smith, unpublished notes, 1920–21—"Asplenium cyalo- sorum"). and Polysthenum murale (Turner 1975; Turner and Bell 1973; Nancy Turner unpublished notes on Haida, 1971). D. spinulosa, D. dilatata, D. austriaca, and D. expansa are considered to be in the same taxonomic complex, as explained later. In most, if not all cases, the identifications were made on the basis of selection and information provided by Native elders.

Potentially all of these species were used but, logically, some citations result from confused or mistaken identifications. In this paper, we present evidence to indicate that the “real” wood fern rootstock—the one normally used as food—
is that of Dryopteris expansa, but that on occasion other, similar types of fern rootstocks were also consumed.

The confusion surrounding the identification of the edible wood fern is exemplified in the unpublished notes of Harlan I. Smith on plant use by the Nuxalk (Bella Coola) and Carrier Indians of central British Columbia. Smith referred in several places to an edible fern called sq’gumilxel ("squaleum"), which had a "... part like a pineapple at the base [that was] used for food." In his Carrier ethnobotany notes, he identified it as Athyrium filix-femina and noted, "Leaves coarser and less bifurcated than the shield fern." In his Bella Coola ethnobotany notes, he identified squaleum as Dryopteris expansa and also attributes the name "Xala’" to this species. Then, he notes: "Trouble. Same species given two different Bella Coola names, one useful for food only, the other used for medicine." His native Bella Coola consultant evidently applied the two native terms to different specimens of the same species. Adding further confusion, a third term, "kanatu," was applied by Smith’s Native consultants to the tops (fronds) of Dryopteris expansa (see previous footnote) and Athyrium filix-femina with a note under the latter: "Trouble. Joshua Moody calls this the same as Shield Fern 7 (Squaleum) with which it was collected; yet that is the same species as 7 (7JM) which he calls squaleum [both of these are actually Dryopteris expansa]."

Elsewhere in his unpublished notes, Smith mentioned two other fern species which were sometimes mistaken for the real squaleum. Under Polystichum munitum, sword fern, he noted: "... This plant was not used for food ... but was [sometimes] mistaken ... for another fern called squaleum. The two forms were distinguished by the leaves as the banana-like parts appear the same and both are easy to pull up. The leaves of the sword fern ... do not die in winter ..." Under an unidentified fern "See et t tana," he noted that this one was "... a little different from squaleum. Sometimes people ... mistake it for squaleum. It is not good food. Squaleum is [a good food] ... Roots same and top same as squaleum. I think squaleum has no sporens and see et t tana has." Smith’s Carrier notes are equally confusing.

As will be seen, research within the last two decades at Bella Coola has resulted in clarification of some of the confusion surrounding sq’gumilxel, but the problems that faced Harlan Smith and the Native people he worked with seem to have been repeated in virtually every area where wood fern was eaten. Furthermore, plant taxonomists have also been confounded in the scientific classification of wood ferns, and the many synonyms and nomenclatural discrepancies for various Dryopteris species have made the problem of identification especially difficult.

The aim of this paper is to resolve, as much as possible, the questions arising from the bewildering and sometimes conflicting array of botanical and ethnobotanical information on the edible wood fern in northwestern North America, and to document the traditional importance of this food in Native cultures. We will summarize the botanical and taxonomic features of the wood fern complex in northwestern North America, and relate the botanical characteristics to the utility of the plant. Then we will review the Native terminology, descriptions, and use of the edible wood fern, using information derived both from literature sources and from interviews with contemporary Native
consultants in various speech communities of the region. Nutrient data from specimens collected and prepared at Bella Coola is provided, as well as use frequency and taste appreciation data. Information on non-food uses and the importance of wood fern in mythology and traditional beliefs is also given.

BOTANICAL AND TAXONOMIC ASPECTS
OF THE WOOD FERN PUZZLE

Narrowing down the species. — The fern species reported in this study to have edible, “pineapple-like” rootstocks fall into five genera. These are annotated and evaluated as follows (see also descriptions in Scoggan 1979 and Taylor and MacBryde 1977):

Cyathea — C. bulbifer (‘Ksan, People of 1980); does not occur in British Columbia (Scoggan 1979); concluded to be erroneous identification;

Thlaspia — T. linnaeiflora (Norton 1981); voucher specimen 661 WSU examined by Adolf Ceska in 1989 and found to be Athyrium filix-femina.

Athyrium — only A. filix-femina (L.) Roth (‘Ksan fern) has rootstocks large enough and distribution wide enough to “quality,” has been identified on occasion as the edible type (see previous entry), but usually rejected;

Polystichum — only P. manicum (Kaulf.) Presl (sword fern) has large enough rootstocks to be the edible type, and has occasionally been suggested as such in literature citations,10 P. braunii (Spaun) Hee (Braun’s holly fern) has rootstocks large enough, but has never been cited in ethnobotanical or ethnographic literature as having been eaten;11

Drynaria — most frequently cited as having edible rootstocks; taxonomic treatments for the genus widely variable (cf. Hultén 1968; Calder and Taylor 1968; Scoggan 1978); some species ruled out because of size or range;12 leaving D. flexuosa (L.) Schott (male fern) and two species of the “Drynaria expanse complex:” D. carthusiana (Vill.) H.P. Fuchsl and D. expanse (K.B. Presl) Fraser-Jenkins and Jermy; (see Walker 1955, 1961; Britton 1952, 1968, 1972; and Widen and Britton 1971 for detailed discussions of the taxonomy of this complex).

Of the Drynaria species mentioned, D. flexuosa was identified in one case (Turner 1973) but the Drynaria expanse complex has been more consistently recognized. The two species from this complex are similar, but D. carthusiana (syn. D. spinulosa (O.F. Müller) Wats) has fronds with more or less parallel sides at their lower part and has a chromosome count of 2n = 164; whereas D. expanse (syn. D. assimilis S. Walker, D. aitata [Hoffm.] A. Gray var. alpina Moore) has fronds more or less triangular in outline, with a chromosome count of 2n = 82. The latter is common in northwestern North America; the former is less frequent, but where it occurs, it may grow side by side with D. expanse (e.g., in Channel Islands Queen Charlotte Provincial Park in northern British Columbia). Of all the species mentioned, the one most frequently and consistently cited as THE edible wood fern of northwestern Indigenous Peoples, when synonymy is considered, is Drynaria expanse.

Native perceptions. — Given the complex situation of so many, widely variable fern species and genera sharing at least some characteristics, it is not surprising that
Native people have often provided varying and confusing identifications and descriptions of the edible wood fern and others they consider to be related.

McLwraith (1948, in his Appendix C), in discussing folk classification of the Nuxalk (Bella Coola) adds another perspective to the problem: "In regard to plants, a difficulty lies in the fact that Bella Coola nomenclature is not always strictly botanical. Two or more distinct ferns, for example, may be grouped together on account of their similar use as food and one name applied to them indiscriminantly ..." A Haida Native elder, the late George Young, stated the same concept in discussing several ferns given the same Haida name54: "One word can mean so many names. It's all in the way the sentence or the subject is brought up. You can have one word for two completely different kinds of plants. ..."

The close perceptual relationship among various ferns is shown in the Nuxalk area by the term qa'wisuts, mentioned previously in the introductory discussion of Hanlan Smith's unpublished notes, which is sometimes applied to the fronds of Athyrium, Dryopteris, Polystichum, and Heterium55 although the rhizomes are usually given different names. The identification of the true edible wood fern, sq'wáltm, must be made from the appearance of the rootstock, not the aerial parts. Nuxalk elder Felicity Walkus once applied the name to specimens of both Dryopteris expansa and Athyrium filix-femina growing side by side56, but when she examined the rootstocks after they were dug up, she stated that only the Dryopteris was the true sq'wáltm. This identification was confirmed by Margaret Siwallace and two other Nuxalk elders. The Athyrium rootstock, they said, was the one called Sæma, which was like that of the edible fern, but smaller, blockier, and covered with dark hairs. Grizzly bears are said to like to eat Sæma, but it makes them cranky (Nancy J. Turner, unpublished notes on Nuxalk, 1981). Margaret Siwallace later stated that there were four types of fern that were almost alike. The one with flabby, round "fingers" (leaf bases) was sq'wáltm, the "flat one," Sæma, was poisonous, and two other kinds are similar to sq'wáltm, and edible, but not quite as good (Nancy J. Turner, unpublished notes on Nuxalk, 1983).

Lillooet consultants definitely excluded Athyrium as the edible wood fern, although one elder called it "a kind of C'shla'se't (Dryopteris). Its big, black "roots" are said to be so tough that even a plough cannot go through them (Randy Bouchard, personal communication to NJT, 1974). One specimen collected with Lillooet elders and said to be the edible kind was identified as D. entehusana57.

In the Skeena drainage of northern British Columbia, a number of different identifications have been made of sa', the plant with edible rootstocks. Athyrium filix-femina and Dryopteris filix-mas plants in leaf were pointed out as sa' by David Green, a knowledgeable Gitksan elder (Leslie M.J. Goitsefield, unpublished notes, 1988). Later in the season, however, he identified Dryopteris expansa as sa', and excluded Athyrium. Another Gitksan consultant, Jeff Harris Sr. of Kispiox, who as a child had frequently collected edible fern rootstocks with his grandmother, pointed out that the edible type was recognized from the rootstock, rather than from the tops. The fern was sought and dug up after the fronds had withered. Ferns with a small rootstock, or ones with small or flattened leaf bases, were called dumtx, a term signifying "non-edible fern." During a field trip specifi-
cally undertaken to identify and collect a, plants of *Allium fili-femina* and *Dryopteris filix-mas*, and a small specimen of *D. escuza* were all classified as *dunx* by Jeff Harris. The last was described as being almost like *a*, but too small. Its broken "fingers" or leaf bases had the distinctive pea green colour of *a*.* It was collected in a small organic soil pocket in the hemlock forest, not in the snowbed or avalanche :the habitat preferred by the Gitksan in their interior geographic location. Larger, more robust specimens of *D. esuza*, found in the snowbed locality, were dug up and pronounced to be *a*, because of the relatively large size of the rootstock, the diameter of the "fingers," and their green color (Leslie M.J., Gottesfeld, unpublished notes, 1988).19

Additional insight into native perception and classification of ferns comes from Gordon Robinson, a Ha!tsia elder from Kitamaat Village. When shown a specimen of *Dryopteris esuza* and asked if it was the edible fern root, he commented, "You can tell if it is the right fern if the 'fingers' are round [in cross-section], pale green inside, and brittle. It grows in the forest on top of fallen logs and on stumps. It grows at the base of slide areas.... You can kick it out of the ground or pull it out easily. Other ferns, you need a pick [to dig up]...." (Leslie M.J. Gottesfeld, unpublished notes, 1988).20 It is significant that when one collects a fresh rootstock of *Allium fili-femina*, the "fingers" are tan inside, woody textured, and triangular in cross-section. In addition, the large, fibrous root system is very hard to pry out of the soil (Leslie M.J. Gottesfeld, unpublished notes, 1988).

**Habitat considerations.**—Locations where the edible fern rootstock grows in adequate abundance and quality for harvesting in British Columbia are generally scattered and infrequent. It is a slow-growing perennial fern and hence may be several years old before it is big enough to harvest. Following are some notes on the best habitats or localities observed for edible wood fern growth and/or harvesting (Native group and literature citation given in parentheses):

- near salmonberry bushes (*Rubus spectabilis*) (Triemshian; German 1896);
- balsam and under cottonwood trees (*Populus balsamifera*) and alders (*Alnus rubra*); wooded locations up to 800 m (Tanaina; Kari 1987; Ray ca. 1980);
- "half way up the mountains" in "meadows" or "ravines" (avalanche tracks), open snowbed communities; best locations had ownership harvesting claims (Gitksan, Wet'suwet'en; Jeff Harris, Sr., Beverly Anderson, personal communication to LMG, 1988);
- plentiful around Kuldo (deserted Gitksan village about 90 km north of Hazelton and around other, modern Gitksan villages; Kuldo people were teased in song about their consumption of the fern rootstocks (Gitksan; "Ksan, People of 1989);
- at the base of big cliffs in avalanche paths; areas frequented by mountain goats, who survive on wood fern rootstocks during the winter (Haisla; Gordon Robinson, n.d.; see note 20);
- higher elevations at the base of snow banks and rockslides (Nuxalk; Turner 1973);
- swampy areas (Mainland Comox; Randy Bouchard, personal communication to NJT from 1973 research);
—Fountain Valley, about 1.6 km past Rusty Creek, called "trees'kaw7 after wood fern (Lillooet; Randy Boucharde, personal communication to NJT from 1974 research).

Because it is so infrequent and because harvesting eliminates an entire plant, care must be taken by those harvesting this food to leave sufficient plants behind in each locality for any future harvests, or entire populations of this historically important food plant could be eliminated.

Native food use of wood fern rootstocks.—A summary of ethnographic reports and native nomenclature for edible wood fern rootstocks is provided in Table 1. As shown in this table, edible wood fern rootstocks were used by virtually all North-west Coast Native peoples of British Columbia, as well as by the Lower Thompson, Lillooet, Nisga'a, Gitksan, and Wet'suwet'en, by the southeast Alaskan and western Washington Indian groups, and even by some Eskimo peoples of Alaska. In all, folk names for this food were used in over 25 different Native languages in the region. Fig. 1 shows the extent of former wood fern use in northwestern North America.

1 Orthography used in original source is given, except ʔ = q; ʷ = w. For simplicity, not all reported terms for Athyrium filix-femina or Polystichum muhsens are included in this table, only those cognate with terms applied to Dryopteris spp. or directly associated with reports of edible rootstocks. |

2 M. Dale Kissagle (personal communication to NJT, 1989) notes that the name for spiny wood fern is reconstructable in Proto-Salish, and hence provides evidence for coastal origins for Salish (cf. Kissagle 1989).
Many descriptions exist of the edible wood fern and its use. The rootstocks with their attached leaf bases have been variously described as "like 2 hands clasped together" (Norton 1981; B. Lane, personal communication, 1984), "like a woody sweet potato" (Kaum, People of 1980), "resembling a bunch of bananas" (cf. Kari 1987; Roy ca. 1980; Turner 1973), "like a pineapple" (Harlan L. S., unpublished notes ca. 1920; Turner 1973), a "big root with little fingers" (Willie Matthews, Haida elder, tape transcript by Nancy J. Turner, ca. 1970), or having many brown "fingers" growing around it (Turner 1973). The "good" fingers are succulent. Figures 2-4 show the characteristics of the edible wood fern (i.e., Dryopteris cuprea).

Gitsaa elder Jeff Harris Sr. described the edible fern rootstock as being about as big as his hand (fist), and noted, "...when you take them out the root tapers down to the bottom, when you dig it out, and crooked. You have to take the little piece of the bottom part out because it's small ... that [leaf base] would be about the size of your little finger ... the banana-like root. You take them off and peel it with your finger ..." (Leslie M.J. Gottesfeld, unpublished notes, 1987). The fern rootstock is described as being greenish inside when raw, but turning to yellowish or orange when cooked (Jeff Harris, David Green, Lisette Naziel, personal communications to LMJG, 1987).

Harvesting.—The rootstocks were usually dug in spring or fall (cf. Kaam, People of 1980). The Nuxalk name for the fourth moon after the summer solstice is called atilzilatxanam (lit. "time to get eq'udfim"). At this time, many of the "fingers" on the rootstock are plump and round, whereas earlier many are flat and no good for eating. Potatoes are dug at this time too, according to Margaret Sivallace (Turner 1973). However, the wood fern rootstocks could be dug out even in December if it was a mild winter, and could be dug from under the snow if necessary. Wet'suwet'en consultants stated that wood fern rootstocks should be gathered in fall after the leaves wither or in the winter (Josephine Mitchell 1987, Madeline Alfred 1988, Lisette Naziel 1987, Sara Tait 1988, all personal communications to LMJG). It was stated that the rootstocks are not damaged by freezing and could be dug from under the snow. A special wooden snow shovel was
FIG. 1.—Extent of former use of edible wood fern (mainly Dryopteris expansa) in northwestern North America. (The heavy dotted line shows the approximate distribution of Dryopteris expansa over the same area.)
used to uncover the plants (Madeline Alfred, personal communication to LMJC, 1988). Gitksan consultants stated that fern rootstocks were gathered in fall, winter, or spring before the fronds begin to uncurl. Plants were located by the "whitish stick sticking up" or the "curly leaf" (fiddlehead). Digging the rootstocks out of frozen ground was laborious, but their availability in the winter season made them a valuable food. Some Tsimshian people say they can be dug at any time of the year, but others say that they are dry and unpalatable during the summer months. Some say the rootstocks are juiciest and most palatable in the fall, others in the spring (Karl 1987).

Since the rootstocks were usually sought after the tops had died down, finding them was sometimes difficult. The Haisla and Heiltsuk people evidently had a unique way of locating them with their feet, as alluded to in their term, t’ipw, meaning "to step, tread onto something; to find fern roots or cattails by feeling with the feet" (Heiltsuk), and in t’ikw, meaning "one’s feet touching the ground (as when feeling for fern roots)" (Heiltsuk) (Brian Compton, personal communication to AJT, 1988; terms given to him by Kitsap elder, Gordon Robertson; see also Lincoln and Rath 1986 for Haisla). It is not clear whether the actual names for the edible wood fern are derived from these terms, or vice versa.23 According to Gordon Robertson (Brian Compton, personal communication, 1988), a special digging stick was used to dig up wood fern rootstocks. It was similar
FIG. 3.—Drynaria expansa, rootstock and fronds, taken at Bella Coola, and identified by several Nootka elders as the edible type of wood fern (left).

FIG. 4.—Cross-section of Drynaria expansa rootstock (right).
to the stick used for other edible "roots," but shorter (about 20-45 cm long) and with a flattened point and a round portion on the upper end similar to a nail head. The stick, called epkax in Haiisa, was pushed into the ground with the foot and then pressed down like a lever to remove the root from the soil. Recently, a shovel would be used for this purpose. Boas (1921) also reports the use of a digging-stick, of yew-wood, for prying up the fern rootstocks, which were then placed into a large basket. The Tanaasa generally obtain wood fern rootstocks by chopping them out of the ground with an axe (Kari 1967).

Harvesting and cooking of the wood fern rootstocks, like the harvesting of most plant foods, was apparently undertaken mainly by women (cf. Boas 1921), but men also dug them (Kisan, People of 1980).

Stoogez—Harlan Smith (unpublished notes, ca. 1920) maintained that wood fern rootstocks "...were always cooked [by the Carrier and Nuxalk (Bella Coola)] the same day they were gathered. They were never kept..." Morice (1893) noted that the rootstocks were not dried, but only eaten fresh after pit-cooking. Once cooked and mashed, the food was kept one or two days, according to Smith's Carrier consultant.

The Wet'suwet'en evidently gathered fern rootstocks for storage as well as harvesting them if needed after snow was on the ground. Elsie Tall of Havigilet stated:

In the old days [the women] would get together and leave Hagwilget to go up to Blue Lake. Above Blue Lake... they would dig a whole bunch of fern rootstocks. Then they would build fires... They would put the fruit [rootstocks] under the rocks to cook it. They would preserve it for the winter. They lined cedar boxes with skunk-cabbage leaves [Lysichiton americanus] and preserved all that fruit in them. They sealed the boxes up and dug the ground like cellars... They would preserve all those things for winter, put them away and save them until the hungry time [like winter]. (personal communication to LMJG, 1988).

The Haiisa of Kitamaat Village also formerly stored fern rootstocks for winter. Gordon Robinson recounted:

In the old days each family would pick ten sacks, or baskets of Tlbasu [fern rootstock], They would bury it in the corner of the long house. Like a root cellar. They broke the base off. It is a useless part. They pick it in the fall... (personal communication to LMJG, 1988).

The Kwakwala'wakw (Southern Kwakiutl) spread wood fern rootstocks out to dry on a mat the day after they were harvested, then cleaned them using a special red-cedar-wood scraper, and stored them in a basket in the rear of the house, behind the fire, for 12 days before they were pit-cooked. After they were cooked, they were stored another four days before being served at a feast (Boas 1921). The Mainland Comox also stored them prior to cooking in a cool, dry place, in an open-work basket (Randy Buchard, unpublished notes, 1973).
The Gitksan, too, commonly store edible fern rootstocks. After they were dug, they might be left in a dry shed or cabin, covered with brush and leaves, for a long period of time, "when other food supplies ran out" (Ksan, People of 1980:79).

In Alaska, Tsimshian people are said to preserve wood fern rootstocks by placing them in an underground cache or by storing them in oil or lard (Kari 1987). The Yakutat people also stored them in a pit cache, and in general stored them in a way similar to potatoes. They also keep well for several months in a refrigerator, according to Ray (ca. 1980).

Traditional cooking and serving methods.—Wood fern rootstocks were hardly ever eaten raw, although the Nuu-chah-nulth people sometimes ate them raw as an antidote for shellfish poisoning. Baking or steaming the rootstocks in a pit was by far the most common traditional method of preparation. Detailed published accounts of pit-cooking them are provided in German (1886:78-79) and Rons (1921:518-523). In the former description, the Coast Tsimshian of southeastern Alaska placed the rootstocks in cooking pits interspersed with damp moss or larch and covered them overnight (about 11 or 15 hours). In Iloa's kwak'wakawak (Southern Kwakiutl) account, seaweed and hemlock branches (Tsuga heterophylla) were used to surround the rootstocks, which were also cooked overnight. Members of the household ate the rootstocks. Similar descriptions of pit-cooking wood fern rootstocks are provided by many others (cf. Morice 1893; Bosis 1923; Haskell I. Smith, unpublished notes on Carrier and Bella Coola, ca. 1920-22; Nancy I. Turner, unpublished notes on Haida, 1970, 1971; Ksan, People of 1980; Cselle M.J. Gottesfeld, unpublished notes on Gitksan, Wet'suwet'en, and Haida, 1957, 1988; Jacobs and Jacobs 1982; Kari 1987). Gitksan elder Jeff Harris Sr. said that the rootstocks were arranged in the pit "... just like putting apples" (placed upright, in growth position) and were covered with hemlock boughs (personal communication to LMJC, 1987). The Wet'suwet'en covered them with birch bark (Leslie M.J. Gottesfeld, unpublished notes 1987). The Tsimshian sometimes wrapped them in birch bark for baking and covered them with sand (Kari 1987). Haida people used to cover the rootstocks with hot embers of a fire and leave them to bake overnight (Gordon Robinson, personal communication to LMJC, 1988). The Haida used to line their steaming pits with shalunk—cabbage leaves. The Carrier were said to use elder bark chips in the steaming pit (Morice 1993). The Mainland Comox cooked the rootstocks they call th'khum (identified as Athyrium filix-femina). Bouchard Coll. No. 44 and No. 006; May 1973, May 1976 V) in a pit, but simply by throwing them directly into a bed of glowing hot coals and ashes from a fire and covering them with several inches of ashes (Randy Bouchard, unpublished notes on Mainland Comox ethnobotany, personal communication 1973, 1975 to N.J.T.). In recent times, people have boiled the rootstocks in water for a long time, until they are tender; sometimes the water is changed during boiling (Kari 1987). One Haida woman suggested pressure cooking them to reduce the cooking time (Ray ca. 1980). In Bella Coola today, pressure cooking is the method of choice for preparing wood fern rootstocks for feasts. The use of the rhizomes as a soup thickener was sug-
gested by Ray (ca. 1980). Some Gitksan people now preserve the rhizomes by canning (Kaan, People of 1980). When not properly cooked, the rootstocks are described as rubbery and hard (Mark Jacobs Jr. of Kitka, personal communication to LMJG, 1988).

Bass (1921:323-324) provides a detailed description of the serving of wood fern rootstocks at a Kwakwaka’wakw (Southern Kwakiutl) feast, which was held four days after the fern roots had been in the house and had been cooked. The roots were considered a “really valuable food,” and were often served with oil and dry silver-salmon spawn to the chiefs of the tribes. A chief could feed and eat the outer fern roots, but was supposed to give away the inner part of the fern root, not to eat it himself, or “he will always waver in his mind about giving away blankets . . .”. After the feast, each guest was given two fern roots to take home to his wife.

There are many other reports of the rootstocks being cleaned, the leaf bases being removed, peeled, and eaten one at a time. Similarly, many reports refer to the eating of the rootstocks with oil, grease, lard, and/or salmon roe (cf. Nancy ), Turner, unpublished notes on Ha ideals, 1971; Turner 1973; Randy Bouchard, personal communication to NT, 1973 for Mainland Comox; ’Kaan, People of 1980; Kari 1987; Brian Compton, personal communication to NT, 1988, for Haida; Leslie M.J. Gottesfeld, unpublished notes on Gitksan, Haida 1987, 1988). The Haida, for example, ate them mixed with eel gruice in a big bowl (Brian Compton, personal communication to NT, 1988, from Gordon Robertson), or ate them with fermented or dried salmon roe (Gordon Robinson, personal communication to LMJG, 1980). The leaf bases, once removed from the main rootstock, were usually peeled with the fingers before being eaten, then dipped into the oil. The Mainland Comox dipped them into seal oil and ate them with dried salmon eggs (Randy Bouchard, unpublished notes on Mainland Comox ethnobotany, personal communication to NT 1973, 1975). The Nuxalk ate them with grease or fermented salmon roe (McBride 1948; Turner 1973). In modern times, the Gitksan ate them with sugar (’Kaan, People of 1980).

Kari (1987) notes that some Tsimshian people state that only the “stem” portion of the underground part is eaten, others that only the “leaf bases” are eaten, and still others that both parts of the rootstock are eaten. Gitksan consultants say both “stem,” and “leaf bases” can be eaten.

The Carrier, after pit-cooking the rootstocks, pounded them up with two stones, the upper one apparently a pestle, and the lower one flat (Harlan L. Smith, unpublished notes on Carrier and Bella Coola, ca. 1920-22). Smith noted that “Sometimes the U’ku’ku’ Carrier Indians went to Bella Coola and traded moc-cans for pestles and other kinds of goods . . .”

Oswalt (1967) reported that the rootstocks of “Dryopteris austris)” were occasionally collected, boiled in water, and added to igaluk, or “Eskimo ice cream.”

Sometimes the rootstocks were simply roasted in the fire, covered with a hot stone, if there were not enough to pit-cook (“Kaan, People of 1980).

Other food uses.—The Tanaina and other southeast Alaskan natives eat the young rootstalks, or “fiddleheads” of wood fern (ph), cooked or steamed, as an early spring
vegetable, and many southeast Alaskan can then for winter use (Kasi 1987; Heller 1976). The Kaaq'ina'l Iidaa are said to boil and eat the “hiddleheads” (of "Thelepteris"); see Table 1) as a vegetable at present (Norton 1981). According to Ray (ca. 1938), fern hiddleheads, commonly eaten among many Native peoples of Alaska today, are not known to be a traditional food. He provides recipes and suggested methods for canning and freezing these greens. Some Tanaina people also used wood fern rootstocks for making beer, a practice they probably learned from the Russians, according to Kasi (1987).25

Survival and famine food.—As recounted by Peter Kalifornsky of the Outer Inlet Tanaina (Kasi 1987:136), the rootstocks were formerly regarded as a good survival or starvation food:

In the early spring one year, the people ran out of food. They divided into two groups, one moving up into the higher country to dig rhizomes for edible wood fern; see Table 1, and the other to dig clams. Those people who lived on ferns regained their strength and gained weight, while those that lived on clams barely survived.

In winter and early spring, the rootstocks had to be chopped out of the ground, after a fire was first built over an area where the ferns were known to grow in order to thaw the ground (Kasi 1987). The Tlingit (Jacobs and Jacobs 1982) and Gitksan ("Ksan, People of 1980) also state that wood fern can be a survival food. "It has warded off starvation more than once." ("Ksan, People of 1980:79). Mark Jacobs Jr. of Gitlaksan (personal communication to LMJC, 1988) stated that perhaps fern rootstocks were eaten sometimes as an ordinary food, but they were mainly used as a survival food by the Tlingit. Gitsam and Wet'suwet'en stories also refer to fern rootstocks as a survival food. A woman who was hastened from Murticetown survived through the winter on fern rootstocks and salmon roe according to a Wet'suwet'en story (Alfred Joseph, personal communication to LMJC, 1986). Jeff Harris Sr. mentioned a Gitksan legend about a period of starvation: "There in the famines some people eat fern rootstocks. They lived. Others go to get xaa' u [henloch combium] but they all died." (personal communication to LMJC, 1988).

The frequency and rate appreciation of wood fern rootstocks.—An interview study of 61 adult Nuu-chah-nulth women in three generations, representing the Nuu-chah-nulth reserve in Bella Coola, was conducted in 1982 as part of the Nuu-chah-nulth Food and Nutrition Programme. Each woman was asked for her family's use for wood fern "root" (and other traditional food species as well), and a score of her impression of her own personal taste appreciation of the cooked root "fingers." Of the 61 women, only six (all elders) reported ever tasting the root food. On a scale of 1.0 (not used) to 4.0 (used more than one time per week when available and in season), the women reported a mean use frequency today of only 1.3 (very low) but in their earlier days they used it at a greater extent, with a score of 2.8 on a scale of 1.0 to 4.0, which represents use of approximately once or twice a month. These women reported never to have preserved or stored the roots (in cellars or otherwise) for later use.
The mean taste appreciation score of the six women was 4.3, in a scoring scale of 1 to 5, with 5.0 being the highest possible (best tasting food), indicating these women enjoyed this food. Details of the methodology are reported elsewhere (Kuhllein et al., 1989a).

Gorman (1896:79) described the taste of wood fern rootstocks as, "slightly sweetish" but "too smoky and tobacco-like in flavor for the average white man's palate, except under stress of hunger." He added, "... I have no doubt it is quite nutritious." The Tzalma also considered this to be very nourishing, as indicated from their previously related use as a survival food (Karl, 1987). Jacobs and Jacob (1982) described the edible portion as being "light brown like squash and tastes about the same." Haida elder Willie Matthews described the cooked "Igers" (leafstalk bases) as "just like potatoes inside" (Nancy J. Turner, unpublished notes, 1971). Ray (ca. 1980) noted that the raw rhizomes of the wood fern ("Droseris dilatata") are bitter, but sweet tasting when cooked. He said they are salmon colored, with texture and taste very similar to sweet potato. The Gitksan people also describe the edible fern as having the same texture and color as a sweet potato when cooked, and believe it to have "considerable food value" (Ksan, People of 1980:79). One Lillooet elder described the taste as "very much like coconut" (Randy Bouchard, personal communication to NJT, 1974).

Nutrient analyses.—During the late summer and early fall of 1982, in the course of a general series of analyses of traditional foods carried out under the Nuxalk Food and Nutrition Programme, approximately 30 wood fern rootstocks were dug with the supervision of Nuxalk elder Felicity Walkus. These were cleaned in the traditional manner by washing with water and then (for convenience) cooked by pressure cooker until soft. The cooked roots were then peeled, and 250 g were frozen together in a plastic bag and shipped to the laboratory. A similar sample was prepared in 1983.

The laboratory samples were mixed with equal weights of distilled, deionized water, blended in a glass container with stainless steel blades and processed through various nutrient analyses. The details of these methods are reported in Kuhllein et al. (1982) and Kuhllein (1989a, 1989b).

Results of the nutrient analyses of the wood fern "root" samples are presented in Table 2, together with reported values for the common potato, baked in the skin. It can be seen that there is reasonably good agreement between the two foods for water, protein, ash, carbohydrates (computed by difference between total weight minus the sum of protein, fat, moisture, fiber, and ash) and approximate energy computations. In contrast, mineral values in fern "root" were much higher for calcium, magnesium, zinc, copper, and manganese, but higher in potato for sodium and iron. The differing values may have been in part due to contributions from the skin of the roots, since it is known that skins of root foods are more mineral-rich than the starchy flesh. These minerals can migrate into the flesh during cooking.

The proximate composition of fern "root" is in good agreement with that reported for Trifolium wormskaldi (springbank clover rhizomes) and Polystichum aspera ssp. pacifica (Pacific silverweed roots) (Kuhllein et al., 1982). For mineral composition, fern "root" was slightly higher in calcium, phosphorus, and

Mental uses of wood fern and related types.—A significant use by the Nuxalk of Dryopteris expansa ("Aspidium cyclosum") was eating the rootstock raw to neutralize poisoning from eating several kinds of shell-fish in the early part
of the summer (presumably paralytic shellfish poisoning, but not proven as such) (Smith 1928). The physiological basis for this application is not clear. Possibly, the inflammation relates to the use of *Drynaria* felix-mas rootstocks as an anthelminthic or vermifuge drug (Claus et al. 1970). Incidentally, we could find only one reference to use of a fern as a vermifuge by Native peoples in the study area: Smith (1928) noted that the Northern Carrier boiled the root of a fern ("species uncertain") and drank the decoction for worms.

Most other medicinal uses of wood fern and its relatives were as poultices for skin ailments. The Clallam of Washington pounded the roots of *Drynaria austriaca* and used the pulp as a poultice for cuts (Gunnar 1973), and the Inland Tsimshian boil the rootstocks of *uh* (apparently including both *Drynaria cartilaginea* and *Attyrum felix-femina*) in water and use the liquid as an eye wash and as a wash for cuts. The decoction is also drunk for tuberculosis, kidney troubles, and respiratory problems such as asthma (Kan 1987). The Haida used the boiled, mashed rootstocks of sword fern (*Polystichum munitum*), which were called by the same Haida name as "*Drynaria austriaca*" by several Native consultants, as a poultice for cuts and swellings (Nancy J. Turner, unpublished notes, 1973).

Other, miscellaneous uses.—The thin, wiry roots of "*Drynaria austriaca*" were sometimes used by the Kwakwaka'wakw (Southern Kwakiutl) as the burning material in a "slow match." They were enclosed within a clam or mussel shell and ignited. The shell could then be buried and the fern roots would smoulder for several days (Turner and Bell 1973).

The Upper Halkomelem people sometimes gather the fronds of the "mountain fern" (*Drynaria* sp.) for use by florists (Galloway 1982). The Western Eskimos of Alaska have used the fronds of *Drynaria austriaca* in recent years to decorate the inside of the church and the graves in the cemetery on certain church holidays. Additionally, ferns were described as having adorned some of the ceremonial masks used by the Kodiak Island Eskimos (Osvald 1957).

Gunnar (1973) notes that the Snohomish (Lushootseed) soaked the leaves of *Drynaria austriaca* for a hair wash. The Haida used the dried fronds for bedding and to inter-layer between drying fish to prevent molding (Nancy J. Turner, unpublished notes, 1973).

**Mythology and traditional beliefs.**—Edible wood fern is featured in several myths within the areas where it was used. There are at least two myths explaining the origin of this food, one "Tlingit and one Lower Lillooet. In the Tlingit account, the head of an orphan girl entangled by a landslide near her village was transformed into a fern root (*kuuldf), while her body became a ground hog (marmot) (Swanton 1909:180)." In the Lillooet episode, part of a much longer, more complex story called *Kiyaim*, a blind old woman was transformed into a wood fern plant by her angry husband because she had allowed their grandson to be stolen. He took her up and jammed her nose into a log, saying ..., "There! You shall become a *Tlalkis* [wood fern]. By and by people will eat you ..." (Hill-Tout 1905:177)."
There are two other short episodes in Tlingit mythology concerning the wood fern. One is about its transformation by Raven, told within a long story of how Raven changed people, animals, and plants into their present form (Swanton 1909:16). The other is about a man who was aided in becoming a hunter by a supernatural mountain being. The man was warned that the green fern roots, which grew wherever there are grizzly bears, were not to be used because they belonged to the mountain being (Swanton 1909:258). Other mythical accounts of wood fern have not been previously published.

The following story about Sq'wil'm, Wolverine, and Raven is shared in Kiksiquit (Naxalk, or Bella Coola) and Heiltsuk mythology, according to the late Margaret Siwallace, whose father, Joe Saunders, had told it to her around 1940:

Wolverine went up to a certain mountain (above Kiksiquit) to hunt for mountain goat. He was sitting by the fire roasting Sq’wil’m on a stick when the supernatural being who is the “go-between” between mountain goat and people (he is half goat, half person, sort of like the mythical centaur) came along. “What are you doing?” he asked. Wolverine lied, “Roasting mountain goat kidney.” Then the goat-person tested his bow. He shot in several directions and each time he shot a mountain goat. He pulled away the fat from around the stomach of each and gave it to Wolverine. Wolverine took it home and gave it to his children, who had a great time roasting it over the fire and eating it. Raven’s children were nearby and wanted some, but they were not invited to eat. Wolverine told Raven how he got it.

The next day, Raven decided to get some mountain goat fat for his children. He went up and was roasting some Sq’wil’m over the fire when the goat-person came. However, when he asked what he was doing, Raven answered the truth—roasting Sq’wil’m. Goat-person did not test his bow and Raven got no mountain goat fat from him. He went down the mountain, wondering how he would feed his children. He slit his own breast open and removed the fat from his front. He gave it to his children telling them it was mountain goat fat. But when his children held it up to roast it, he kept calling, “It burns, it burns, it burns!” When they ate it, he still said that. (The late Margaret Siwallace, personal communication to NSF, 1983.)

According to Gitksan elder Jeff Harris Sr., people used to tell stories about fern root in the community house. He has given permission for the following story to be reported here, in his own words as told in English:

There was a family of four: a man and his wife and two children. The older one was a girl and the small one a boy of three or four. When they ran out of food in the spring time there was still snow upon the ravines. They used a wood paddle or shovel or spade, sin’al, to scrape aside the snow (on the “ravine”). They find a. The stems still come up under the snow. They gather it all up and roast it under fire.
The girl is looking after the little boy at the camp while the mother is [about 30 m] from the camp. The little boy cries. The girl is looking after the boy. The girl hollered to her mother, "The baby is crying." The mother replied, "Mi' ooda lus todzin, MF' ooda." She meant, put some ash in the ashes, prepare a bit of food for the boy.

The girl got it wrong and threw her brother in the fire. She boilled,
"I threw him in the fire but he kept on coming back!" The boy got burned.

The story continues with an account of how a stranger dressed in black, a bear person, appeared and told the family how to use bear oil or fat on burns as an ointment or medicine. Harris explained that rendered bear fat could be used as grease when eating fern root, which may explain the linking of the story of the bear offering his fat to the eating of fern root.

The importance of wood fern rootstock as a winter food for the Gitksan is indicated by its adoption as a major crest by the house of Wessalaalaala of the Gileanet (Fireweed Pimney) from Kispiox. The crest is called Wii' Aa' ("giant wood fern rootstock"). It refers to a story about a giant wood fern root which was accidentally discovered near Kissegas by a man after being mistaken for firewood. A large pile of wood had been gathered and burned all night. In the morning the giant fern was discovered in the ashes. (This may be a reference to the discovery of how to cook Dryopteris rootstocks.) The present holder of the crest is Alvin Weget of Kispiox village, who inherited the crest and a button blanket which displays the crest (Alvin Weget, personal communication to LMG, 1988).

Photographs taken by Marius Barbeau (1929:86-87) show two totem poles from Kispiox village in the 1920s bearing the "mountain fern crest" (Wii' Aa'). The first (Fig. 5) shows a geometric pattern of diamonds purported to be the "mountain fern crest" (ts'a'a), probably the spiny wood fern. Modern residents of the village do not appear to recognize this crest. The second pole, still standing today (in a different location), stood beside the first, and figures the Wii' Aa' crest in more representational fashion: a series of upward painting figures in several tiers topped with four or five stylized fiddleheads (Fig. 6).

Boas (1932:227) reports a relevant traditional belief held by the Kwakwaka'wakw: "When fern roots (Dryopteris spinulosa, te'a'a) are steamed in an oven, an immature girl, if possible the daughter of the woman who cooks the roots, must tramp on the mat to press the whole down firmly." In a previous description of pit-cooking the ferns (Boas, 1921:321) he stated that the filled cooking-pit should be trampled by "a woman who has had just one husband, and whose husband is still alive, and who has never been a widow, and whose monthly period terminated at least eight days before." He also noted that all members of the household in which the fern rootstocks were being pit-cooked should abstain from sexual intercourse during the night.

CONCLUSIONS

Although several different botanical identifications have been published for the edible wood fern rootstock, used as a food and emergency ration by Native peoples in western North America from Washington to Alaska, evidence sug-
FIG. 5.—Pole from Kispiox ("Kispayats") Village, showing at the base a geometric pattern of diamonds purported to be the "mountain fern crest" (Wii Ak), probably Dryopteris exquisitissima (left). Modern residents of the village do not appear to recognize this crest. FIG. 6.—Pole from Kispiox Village, showing the Wii Ak crest in more representational fashion: a series of upward pointing fingers in several tiers topped with four or five stylized fiddleheads (right).
gests that the major species involved was *Drynaria quercus*, a member of the *Drynaria nuttallii* complex. Within this species, the largest specimens were pre-
ferred and selected. Other species with similar appearing roots, including *D. constricta* and *D. filix-mas*, and *Polygala rhodocephalum*, were also apparently eaten on occasion. Although *Athyrium filix-femina* has often been suggested as the edible wood fern, most knowledgeable Native elders who have examined its rootstock clearly reject it as an edible type.

Present use of wood fern rootstocks as food is extremely low. In most cases, only Native elders in their sixties or older remember having eaten this food, or when themselves gathered and prepared it. A few elders are interested in obtaining and cooking it “for old time’s sake,” and to enjoy the remembered flavor. Everyone universally comments on the greater convenience and availability of substitute carbohydrate foods like potatoes and turnips. Some potential use for a survival food or an infrequently-used cultural specialty food seems appro-
riate.

Because the distribution of the edible wood fern is scattered, and because harvesting the rootstock for food means destruction of the entire plant, conserv-
ation of wood fern populations should be a primary consideration in any program involving future food use of wood fern.

NOTES

1 J. P. Herrington’s notes (ca. 1910) are at the Smithsonian Institution, Washington, D.C. (Rel 15, frame 0472). Ethnographer T.T. Waterman confirmed the same term for this fern about a decade later (Barbara Lane, personal communication to N.T., 1983).

2 Four different unpublished manuscripts of Harlan I. Smith are cited. They contain unnumbered pages, many of which are duplicated under one or more different titles. Handwritten notes have been added to typed text with occasional dated entries. Comments on Pteridophyta data date mostly from 1920-1922. The original manuscripts are all held by the National Museum of Civilization in Ottawa, Ontario (formerly National Museum of Man), and are entitled: “The Material Culture of the Carrier Indians of British Columbia, Part I. Introduction to Food Utilization,” “The Material Culture of the Carrier Indians of British Columbia, Part 2, Securing Food to Dwellings,” “The Uses of Plants by the Bella Coola Indians of British Columbia, Vol. 1,” and “The Uses of Plants by the Carrier Indians of British Columbia, Vol. 2.” His Native consultants included Captain Schooner (Nuxalk, or Bella Coola speaker, born ca. 1849), Joshua Moody (Nuxalk speaker, born ca. 1860), Louie Hall, and “Pretty Charlie,” (probably Ulkatcho Carrier speaker Charlie West). Voucher specimens made by Smith of the ferns mentioned in his notes are at the National Herbarium in Ottawa (CAN). They were examined by Adolf Csika during the present research.

3 The following unpublished notes on the Haida and Nuxalk made by Nancy J. Turner, and in her possession, are cited in the manuscript: Turner 1970 (Haida), Turner 1971 (Haida), Turner 1981 (Nuxalk), Turner 1983 (Nuxalk), Turner 1988 (Nuxalk).

4 Harlan I. Smith’s unpublished notes, ca. 1921: “Lady Fern, Asplenium cuneatum” (collections made by Smith: 8th June 7, 1920 [CAN 525 607]; 8th June 22, 1920 [CAN 525 608]); both were confirmed by Adolf Csika as *Athyrium filix-femina*. 

5
Halen L. Smith's unpublished notes: "Shield Fern, \textit{Asplenium polyodon}" (collections made by Smith 755014 June 18, 1921 [CAN 525 615], and 77774 July 11, 1921 [CAN 525 616].) Both identified by Adolf Csáki as \textit{Asplenium crumena}.

Halen L. Smith's unpublished notes: "\textit{Asplenium filix-mas}" (Clinch Coll. 75550, June 18, 1921 [CAN 539 333]; Identified by Adolf Csáki as \textit{Asplenium filix-mas}. but specimen is the tip part of an old frond, early misconception for \textit{Dryopteris filix-mas}.—AC.

This term, \textit{asulam}, is sometimes applied as a general term for ferns in North Wakashan languages such as Kwakwala (Southern Kwakiutl) and Haida, or to \textit{Polypodium} minus specifically. It is known 1970, Lincoln and Roth 1969, Brian Conant, personal communication to NJT, 1989.

Two ferns, one called \textit{da sin a chín} and one, \textit{oh, ak, aš chín}, or \textit{ah chín}, are mentioned in Halen L. Smith's unpublished Carrier notes. The former term, listed under "Lady Fern (\textit{Athyrium filix-femina} Super.)," has a hand-written notation: "Leaves coarse and less bifurcated than the shield fern."
The latter, under "Shield Fern," states: "... has spores and is finer, more bifurcated than \textit{Asplenium} ... This Shield fern roots used for food found 20 miles away (in the Bella Coola Valley) ... roots called \textit{oh}, ... it always has little [hairs?], can't read handwriting" like where housewife's come off stem, there are none on the \textit{sin a chín}.

Smith noted that \textit{aš chín} was the same as \textit{asulam} in Bella Coola, but also reported that one of his Native consultants (H.I.S.) could not distinguish between the two types.

Another aspect of the confusion is seen in Frank Boas's classic work, The Ethnology of the Kwakiutl (Boas 1921), where meticulously reported accounts are given in English and Kwakiutl of the harvesting, preparation, and serving of Kwakiutl foods. Cultural features of at least these edible fern species are described, all called in the English version simply "fern root." According (\textit{Podocarpus macrophyllus})—\textit{algúms}. Native term (\textit{Polypodium rhizophyllum})—\textit{asulam}, and wood fern (\textit{Dryopteris caulescens}) or \textit{D. spinulosa}—\textit{filik-nal}. One must consult the Kwakwala text to learn which species is being discussed. In fact, in at least one case (Boas 1921: 526), the scientific identification for the fern being discussed, given as \textit{Dryopteris rhizophyllum}, does not match the Kwakiutl name used, \textit{asulam} and the information given also matches \textit{Polypodium}, since it refers to the "fern root" being herb in the month of a hunter to alleviate hunger and thirst, a common practice for this latter species.

A small, related species of rocky areas, \textit{P. lateralis} (D.C. Eaton) D.H. Wagner, sometimes included as a form of \textit{P. aquilinum}, extends in our area only to the western part of Vancouver Island and the Strait of Juan de Fuca, its rootstock is very small, and its use as food is unlikely.

Another fern, whose middens were eaten by Native peoples of the Maritime, Maltacwa, and Haida (\textit{L. Ted. (eastern term).}) also occurs in some locations where edible wood fern rootstocks are used (i.e.,\textit{, pink tide and north of Kitimat}) but its range is quite restricted, now, to our knowledge, has er been cited in the ethnobotanical and ethnographic literature of western North America as having been eaten here.

\textit{Dryopteris fragrans} (L.) Schott (\textit{fragrant shield fern} or \textit{fragrant cliff fern}) can be excluded from the species possibly used as food, because of its small size and its limited distribution on dry limestone cliffs in northern British Columbia and Alaska (cf. Scroggan 1998; Halence 1986). \textit{Dryopteris arguta} (Kaulf.) Watt (\textit{coastal shield fern}) is likewise excluded
because it is restricted to southeastern Vancouver Island (near NanOOSE Bay) and the adjacent Gulf Islands (Straley et al. 1983), whereas the major reports of use of edible wood fern are outside of this range. Dryopteris cristata (L.) A. Gray is a relatively rare species of the British Columbia interior, and has not been collected at all along the coast (Straley et al. 1983).

Some authors, including Walker (1961), questioned correctness of the name D. casteur- simne, but we followed the nomenclature suggested by Heywood (1964) and generally accepted in the recent taxonomic literature (Page 1992; Lellinger 1983).

In a taped interview with Nancy J. Turner, 1971. The ferns being discussed included Athyrium filix-femina, "dryopteris americana" (D. expansa), "Athyrium rupestre, and Athyrium sparsis, all of which George Young called, at times, dryopteris. D. expansa was also called "seal's foot," Pteridium aquilinum was called "seal's foot," and some specimens of Athyrium filix-femina, Dryopteris expansa, and Polystichum munitum were called tidgeweed, or skiaq (lit. "tail"), which he specified to the larger, edible rootstocks. They are also sometimes called "naitkay" (lit. "black-beaver's tail"). The smaller specimens of these species and Polystichum munitum, with rootstocks too small to eat, were sometimes called "nait-kay" (lit. "scabby-root") (Florence Davidson and Willie Mathews, Musket speakers, in Nancy J. Turner unpublished notes, 1971).

Margaret Siwallance used this term specifically to refer to the dead fronds of Pteridium (baked fern), but recently she applied it to the dead fronds of any fern, or even dead leaves of any tree (Kendy Bouehard, unpublished notes, 1974).

Voucher specimens at Royal British Columbia Museum Herbarium: Turner 1394—V 127,677 (Athyrium filix-femina) and Turner 1699—V 127,678 (Dryopteris expansa).

The following unpublished notes made by Leslie M. J. Gottesfeld, and in her possession, are cited in the manuscript: Gottesfeld 1987, Gottesfeld 1988 (Citkan).

An additional fern to be found in the preferred habitat of a, namely a mountain snowbed or avalanche chute, is broomfern (Pteridium aquilinum). This fern was distinguished by Jeff Harris Sr. and Billy Blackwater of K'upix as being shoulder high and was called haka haka're. Both haka haka're and davem are said to have larger leaves than a (Leslie M.J. Gottesfeld, unpublished notes, 1988). Voucher specimens of a collected by Gottesfeld have not yet been accessioned at the Royal British Columbia Museum Herbarium (V), but all were identified or verified by Adolf Cetsa, Jan. 30, 1989 as D. expansa: TM 204, TM 205, Eth 25, Eth 24, Eth 30.

This information was mentioned elsewhere by Gordon Robinson in a handwritten manuscript, transcribed from a notebooks of a speech by him on Haisla culture, on file at the Nislev Indian Teacher Education Program Library, University of British Columbia, Vancouver (no date given).

Various other Haisla and Heiltsuk terms relating to the edible wood fern were recorded by Brian Compton from Gordon Robertson. These include terms meaning "soft end of edible fern root," "to eat edible fern root," "to go after edible fern root" (all Haisla), and "to eat fern roots" (Heiltsuk). There are also terms (Haisla, k'n'laak; Heiltsuk, K'Edla, K'Edla, K'n'laak) apparently referring to the fronds of wood fern, or "a long green fern species" (Lincoln and Rah 1986) which were used to cover salmon in a canoe to prevent them from drying out.

23 Nancy J. Turner (1973, unpublished notes, 1983) reported that Margaret Sivallace stated that people wishing to lose weight ate wood fern rootstocks raw, but Herriet Kuhleitn, who also spoke to MS about this, felt that she meant the rootstocks took so much energy to find and dig out that by the time you got enough for a meal, you would lose weight. Kent (1987) (see section, Survival and famine foods) implies that it is possible to gain weight from eating (cooked) fern rootstocks.

24 This dish is made from seal oil and commercial lard mixed with berries, a little sugar, boiled fish, and certain greens such as sour dock, horsetail, mare's tail, or wood fern. In the winter it is stored in the cold so that the oil congeals, and it is served in a solid state. It is a favorite dessert at Napeents, and an adult usually will consume two to three measuring cups full at a sitting (Osvald 1957).

25 The brey, called oil brey, was made by boiling the rootstocks and cooking them for several hours in a gallon (5 l) of water. Hops were added, either before or after the rootstocks had finished cooking, and afterwards, a pound (0.5 kg) of sugar and a pound (0.5 kg) of mashed potatoes or raw cornmeal was added, followed by five more gallons (23 l) of water, and, finally, the yeast (this is one version of a rather variable recipe) (Kent 1987).

26 Swanton noted "evidently fragmentary" for this myth.

27 Hill-Tout (1905) identifies "Ts'elxw" only as "some kind of trailing plant or herb that grows on logs in the forest."

ACKNOWLEDGEMENTS

We would like to acknowledge the following aboriginal consultants for their contributions to this paper: Jeff Harris Sr., Solomon and Kathleen Matrden, Art Matthews Sr. and Kathleen Matthews; Alvin Weget, and Fern Stringer (Gikxsan); Andrew George, Leonard George, Josephine Mitchell, Lilian N爱好, Kathryn N爱好, Sara Tsai, Madeline Alfred, Alfred Joseph, and Ilse Tait (Wat'suwet'en); the late Dr. Margaret Sivallace and Felicity Wilkins (Nuxalk); Gordon Robinson (Klikitat Hatles; interviewed by Brian Compton-Irwin and Philip Robinson and Lloyd Stueb (Hatles); George Young (Heiltsuk); Mark Jacobs Jr. (Tlingit); Johnny Joe (Tlingit); interviewed by Randy Bouchard, 1978; Bill and Rose Mitchell, and Jeanie Doting (Mainland Comox; interviewed by Randy Bouchard, 1978). Many others provided information through published sources, and are acknowledged by name in most of these. Native language translators included Doris Michell and Cecilia Lapalme (Wat'suwet'en) and Beverley Anderson and Barb Seonit (Gikxsan).

Samples for nutrient analyses were collected at Bells Cove by Sandy Burgess, Sarah Saunders, Dana Lepley, Aaron Hans, and David Hunt.

We are also grateful to the following people for their help in providing information and/or editorial advice: Randy Bouchard and Dorothy Kenedy of the British Columbia Indian Language Project; Brian Compton; Dr. Eugene Hurra; Dr. David French; Dr. Barbara Lane; Dr. M. Dale Kincaide; Robert B. Turner; Dr. Richard Hobbs; Robert Tyhurst; Beverley Anderson; and Allen Gottsefield. Financial support to LMG for various parts of this research was provided by the Gikxsan-Wet'suwet'en Education Society, the Gikxsan-Wet'suwet'en Traditional Medicine Project, the Kyuhook Wetul Education Society, and the Secretary of State.
The National Museums of Canada, Canadian Museum of Civilization, Ottawa, Canada, is acknowledged for permission to quote from the Herbarium’s unpublished notes (see Note 2 for details). The herbarium of the National Museums of Canada, Canadian Museum of Natural History, Ottawa (CAN), and Dr. K.M. Fryer and N.J. Shchepetsnik (Collections Manager), are acknowledged for the loan of Harlan Smith’s voucher specimens of *Dryptis* and other forms. The staff of the University of Washington herbarium (WTU), and Leslie Kennis and Jean Kerik at the Royal British Columbia Museum’s herbarium (V) are also acknowledged for their help.

BOOK REVIEW

This impressive volume reports on the findings of an international meeting held in Chiang Mai, Thailand, from 21-27 March, 1988. Sponsored by the World Health Organization (WHO), the World Conservation Union (IUCN), and the World Wildlife Fund for Nature (WWF), it brought together experts from 56 countries to "exchange views on the problems, determine priorities and make recommendations for action" regarding the conservation of medicinal plants.
