# **Background and Aim**

The neonatal mortality rate in low- and middle-income countries (LMICs) remains high. The shortage of healthcare workers has been recognized as a contributing factor. In LMICs, parents are vital partners in improving neonatal outcomes. Parental involvement may be especially important for those sick & small neonates who require hospitalization after birth. We performed a systematic review to evaluate the impact of family participation in the care of hospitalized neonates in LMICs.

#### Methods

Six databases were searched from inception to June 2020. Randomized & non-randomized trials were eligible if parents performed ≥1 roles traditionally done by healthcare staff. The primary outcome was hospital length-of-stay. Two reviewers performed study selection, data extraction, & bias assessment.

Respiratory support a. Length of stay Low (RoB 2 or ROBINS I) b. Readmission h. Neurodevelopment

Fifteen studies (6 randomized, 9 non-randomized) from 2 lower-middle and 4 upper-middle income countries were included (Fig. 1 & 2). Trials were heterogeneous in terms of study design, type of family participation and outcomes. Most trials (n=13) had a high risk of bias (Fig. 2). Families participated in a range of activities, including checking for danger signs, monitoring intake and output, and bathing. Family participation did not consistently reduce hospital length-of-stay (n=10) but did improve neonatal mortality (n=7), growth (n=9) and parental well-being (n=5). No significant adverse effects were reported.

#### f. Morbidities

Family participation did not consistently improve length-of-stay but had positive effects on other outcomes. The overall quality of evidence is low. No studies were performed in low-income countries. The evidence is insufficient to recommend a specific type of family involvement.

Conclusions

c. Mortality

e. Growth

d. Breastfeeding
